

# Cooking Largemouth Bass

*Micropterus salmoides* · kitchen guide

From legal fish to boneless meal

## START WITH A LAWFUL, COLD FISH

Confirm the live Wisconsin DNR rule and consumption advisory for the exact water, species, length, and date. Kill a retained fish promptly; do not let it suffocate slowly. Bleed only where lawful and practical, then place it in a draining ice slurry or on ice. Keep raw fish at or below 40 °F; wash hands, knife, and board after contact with viscera.

## Keep or release?

|                      |                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Legal floor          | May 2, 2026–Mar 7, 2027; 14-in minimum; bass daily bag 5 combined on both lakes.                                            |
| Preferred table fish | A legal lower- to mid-size fish; release large adults.                                                                      |
| Why                  | Smaller legal bass portions are milder and large fish contribute disproportionately to spawning and can carry more mercury. |

**Legal is not the same as desirable.** A fish may be lawful yet a poor choice because it is a large breeder, exceeds current meal advice, or cannot be chilled and used promptly.

## Dispatch and field care

1. Use a decisive percussive blow to the skull immediately above and just behind the eyes. Follow with a spike or narrow knife into the brain cavity.
2. Confirm loss of rhythmic gill movement and eye reflex. If either remains, repeat immediately. Cut the gill arches only after insensibility.
3. Keep the fish shaded, clean, and cold. Do not soak flesh in warm lake water. At home, work in small batches and return finished portions to ice.

Clean without contaminating the flesh

| Pause at the plate · what must be true? |                                                                                                                                                                                                       |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Before the opening                      | Fish is still at or below 40 °F; clean and waste trays are separate; the knife tip cannot reach the organs at the planned depth.                                                                      |
| After the opening                       | Viscera came out intact; no green gall stain, fecal material, or abnormal odor is present; kidney tissue is gone.                                                                                     |
| If not                                  | Stop. Isolate the affected side, wash hands and tools, and trim a generous contaminated margin. If condition or time warm is uncertain, discard rather than trying to cook safety back into the fish. |

1. **Set up.** Flexible sharp fillet knife, cut-resistant glove on the non-knife hand, scaler or spoon if needed, pliers, clean towels, two trays.
2. **Scale or skin.** For skinless fillets, do not scale. Fillet first, lay skin down, and slide the blade between skin and flesh. Trim the dark lateral strip and belly fat.
3. **Open shallowly.** From vent toward the throat, lift the belly wall away from organs and use the tip only. Remove viscera intact. Avoid puncturing the gall bladder; trim and rinse any contaminated tissue.
4. **Kidney line.** Scrape the dark tissue along the backbone and rinse briefly with clean potable water. Pat dry. Never use soap on food.

| Parasites and raw fish                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Freezing and pickling are not substitutes for a validated parasite-control process. Cook wild freshwater fish to an internal temperature of 145 °F, or until opaque and separating easily, unless following a qualified food-safety process. Discard abnormal-smelling or badly diseased flesh; when uncertain, do not eat it. |

## Species-specific first cuts

---

Cut behind the gill plate around the shoulder, turn at backbone, and run to tail. Lift the fillet and sweep over broad ribs; avoid opening the gut cavity with the knife tip.

### Cut checkpoint

Before turning the blade, ask: *Can I feel the backbone under the edge, and is the edge pointing away from my off hand?* After lifting the fillet, compare both sides. A ragged frame with meat still attached means the blade angle was too steep; recover that meat with short strokes instead of sawing blindly. A cut gut means stop, clean the station, and reassess the edible margin before continuing.

## Bone map and deboning

---

*Left: ribs and short forward pin-bone row. Right: keep the blade nearly flat while fingertips locate the remaining pins.*

1. Keep the skin side down so the blade can ride on, not through, the bones.
2. Remove the rib cage with a shallow sweep, sacrificing as little belly meat as possible. Run fingertips both directions along every cut surface.
3. Locate pins by brushing head-to-tail and back. Pull firm bones or V-cut the centerline ahead of the point where pins disappear.
4. Portion only after a final fingertip inspection under a bright light. Bones become harder to locate once batter, crumbs, or sauce is added.

| Diagnose before coating     |                                                                            |                                                                                           |
|-----------------------------|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| Finding                     | Likely cause                                                               | Correction                                                                                |
| Bone tips remain            | Only one fingertip direction was checked, or the V/channel was too narrow. | Brush both directions under bright light; recut only the marked line.                     |
| Useful meat stays on ribs   | Blade was held too upright.                                                | Lay it nearly flat and make a second shallow sweep; never cut toward the supporting hand. |
| Fillet tears while skinning | Flesh or board is warm/wet, or the blade rose through the meat.            | Rechill, dry the grip end, flatten the blade, and restart from a sound edge.              |

| Trim map                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remove skin, rib membrane, belly fat, and dark lateral tissue. These trims reduce stronger flavor and some fat-associated contaminants, but do not remove mercury. |

## Prepare before heat

- Pat portions dry. Equal thickness matters more than equal weight.
- Cut thick shoulder and thin tail into separate portions. A brief milk soak changes flavor but does not make unsafe fish safe.
- Refrigerate while the pan, oven, or grill heats. Marinate under refrigeration; discard marinade that contacted raw fish unless boiled.

| Record before heat | Thickest piece | Thinnest piece | Batch start |
|--------------------|----------------|----------------|-------------|
| Thickness / time   | _____ in       | _____ in       | _____       |

| Plan an even batch                                                                                                                                                                                                                                                                                                                                                                      |           |             |                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|-------------|-------------------------------------------|
| <p>Arrange the portions before heat and mark the thickest center in the sketch frame below. Which piece should be checked first? Which thin piece may need to leave the heat early? State the observation—not crust color or elapsed time—that will trigger each decision.</p> <div> <div>Sketch portions in pan / rack order; label thickness and probe entry</div> <div></div> </div> |           |             |                                           |
| Piece / position                                                                                                                                                                                                                                                                                                                                                                        | Thickness | First check | Predicted action if below or above target |
|                                                                                                                                                                                                                                                                                                                                                                                         |           |             |                                           |
|                                                                                                                                                                                                                                                                                                                                                                                         |           |             |                                           |

## Two dependable methods

### Black-pepper skillet bass

Sear dry, lightly oiled portions; lower heat after browning and finish to 145 °F without repeatedly turning.

### Tomato-herb baked bass

Bake equal-thickness portions under a thin tomato-herb layer; verify 145 °F in the shoulder.

## Measure, correct, prove

1. Insert a clean instant-read probe sideways into the geometric center of the thickest portion, away from pan, rack, and bone. Record the lowest stable reading: \_\_\_\_\_ °F at \_\_\_\_\_.
2. If it is below 145 °F, return only underdone pieces to heat in short increments. Clean the probe, then check a new center. If thin pieces are done first, remove them rather than drying the whole batch.
3. Split the measured thickest piece. The center must be opaque and separate easily, with no translucent core. Run one final fingertip pass over the first serving portion before sauce or garnish hides the surface.

### Final proof

Serve only when four answers are yes: **lawful fish? cold chain known? every portion bone-checked? measured center at least 145 °F?** Move leftovers to shallow containers and refrigerate within two hours. Write the successful thickness, method, time, and center temperature on this guide; that record is the starting point for the next batch, not a replacement for measuring it.

## Current safe-eating advice · checked 2026-07-26

Statewide inland baseline for bass: women under 50 and children under 15, up to one serving/month; women 50+ and men, up to one/week. Lake-specific advice and length can be stricter.

1 serving

adult: about the palm of the hand  
child: about the child's palm

count all fish meals from all sources

## THE QUERY BEATS THE PRINTED SHEET

Wisconsin has a statewide inland baseline and water-specific exceptions. Before eating, use DNR's Fish Consumption Advisory Query for Pine Lake (WBIC 779200) or North Lake (WBIC 850800), and match species and length. People who are pregnant, may become pregnant, are breastfeeding, and children need the more protective category. When advice changes, follow the current query.
