

Lesson 10: Spark Gaps

Gas breakdown as historical physics, not a learner build

Stop line and roles

Learner boundary: isolated battery power only, 12 V DC maximum. No outlets, mains leads, opened appliances, large battery packs, charged power capacitors, ignition coils, sparks, or exposed high voltage. An adult facilitator is not thereby an electrically qualified person.

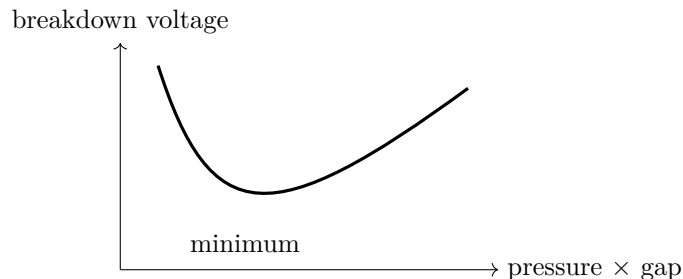

The learner predicts, assembles only the pictured battery circuit, and records. The adult inspects parts, controls power, and stops heat, odor, damage, pain, or unexpected behavior. Work outside this boundary belongs only to a person qualified for that work.

What you need

- This reading
- Printed Paschen-curve sketch
- Pencil
- No energized apparatus

Predict first

Why is “air is an insulator” incomplete rather than simply false?

Investigate

1. Trace the historical sequence: charge separation, increasing field, ionization, conductive channel, rapid energy transfer, recovery.
2. On the curve, mark why breakdown is not determined by gap alone.
3. Identify hazards omitted by a pretty spark photograph: shock path, burns, fire, ultraviolet light, sound, ozone, and radio interference.
4. Compare this mechanism with the low-voltage switch pulses in Lessons 6 and 9.

Explain from the evidence

A gas can become conductive when the field and collision conditions sustain ionization. Breakdown depends on gas, pressure, geometry, and separation. A spark gap is a nonlinear switch, historically useful in oscillators but noisy and hazardous. Nothing in this lesson authorizes construction: exposed high voltage remains qualified-person-only.

Change one thing

Write a museum-label explanation of a historical spark transmitter that includes both energy flow and why it is unsuitable for learner replication.
